Introduction to Computer Network Proj3 Report 0416324 胡安鳳

Exp1 UDP packets

1.

Select the UDP packet. How many fields are there in UDP header? Name these fields.

```
Ans: Vser Datagram Protocol, Src Port: 46069 (46069), Dst Port: 1500 (1500)

Source Port: 46069 (46069)

Destination Port: 1500 (1500)

Length: 21

Checksum: 0x20e9 [validation disabled]

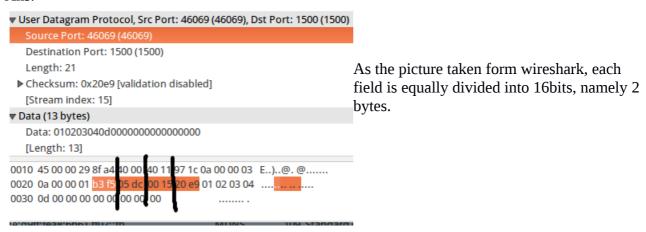

[Stream index: 15]
```

This picture is captured from wireshark, as we can see, there are total of four fields in header, including Source Port, Destination Port, Length of the total UDP data(including the header, unit in byte) and the checksum for error detection(but UDP does not implement error recovery, it has to be done by the application in upper level).

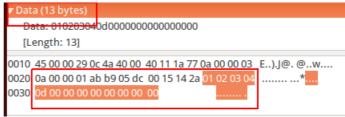

Validating from wikipedia, it is also 4 fields.

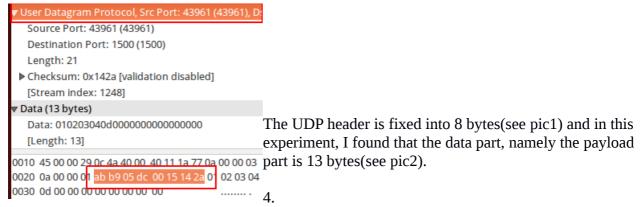

2. Following the first operation, click on the header and observe the display at the bottom of Wireshark window. Determine the length(in bytes) of each field Ans:

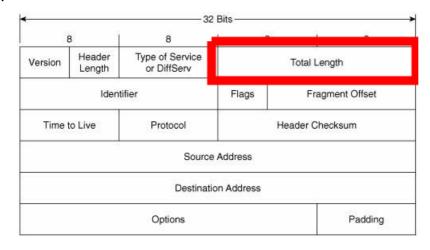

3. Focus on Length field. According to the format:total Length = header + payload, fill in the numbers and explain how you calculate. Ans as follows:

What is the maximum number of bytes that can be included in a UDP payload? (Referred to class notes)

Ans:

In IPv4, the maximum length of packet size is 65535. So, for UDP datagram we have maximum data length as:

65535 bytes - 20 bytes(Size of IPv4 header) = 65515 bytes (including 8 bytes UDP header) **And finally the payload should be 65515 – 8 = 65507 bytes**

5. What is the largest possible source port number? (Referred to class notes)

Ans:

														ι	JDP	Head	der
Offsets	Offsets Octet 0					1											
Octet	Bit	0	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15
0	0	Source port															

2^16-1=65535

Exp2 TCP packets

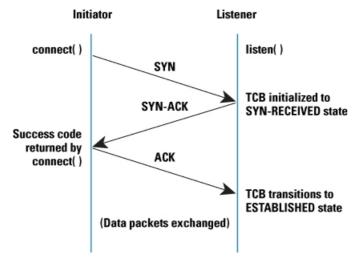

1.

root@icn201/fall:"/proj3# ./tcpclient Please Input Server Address: 10.0.0.1 Hi,this is server. root@icn2017fall:"/proj3# ■

IP Addr Port
Client 10.0.0.3 8700
Server 10.0.0.1 38226

2.

Observing the experimental result, find the segments of "Three Way Handshake," and answer the following questions.

(a)What are the Sequence and ACK numbers in each of the segments?

Anc.	
Allo.	

10.0.0.3	o ₹ 10.0.0.1	TCP	74 38226→8700 [SYN] Seq=0 Win=29200 Len=0 MSS=1460 SACK_PERM=1 TSval=2655519 TSecr=0 WS=512
10.0.0.3	2 nd 10.0.0.3	TCP	74 8700→38226 [SYN, ACK] Seq=0 Ack=1 Win=28960 Len=0 MSS=1460 SACK_PERM=1 TSval=2655520 TSecr=2655519 WS=512
10.0.0.3	3rd 10.0.0.1	TCP	66 38226→8700 [ACK] Seq=1 Ack=1 Win=29696 Len=0 TSval=2655521 TSecr=2655520

1st part SEQ1=0 ACK1= No (No one has transmitted data to client yet, the 3-way handshaking is just about to begin)

2nd part SEQ2=0 (I send my SEQ data to the client host)

ACK2=1(I got client's SEQ0 data and I expected to get the client's next sequence which is 1) 3rd part SEQ3=1 (I send my SEQ data to the server host)

ACK3=1(I got the server's SEQ0 data and I expected to get the client's next sequence which is 1)

(b)Do these three segments

contain any data?

Ans:

No the real data transfer **happens when PSH flag is set**

Reference to:

https://read01.com/zh-tw/dE6deN.html#.Wi0lqHaGOIY

3. Find segments in which the FIN Flag field is set. Explain the purpose of these segments.

Ans:

The packet with FIN flag indicates the TCP connection should be terminated.

Why is the FIN flag in TCP called FIN?

FIN is an abbreviation for "Finish"

In the normal case, each side terminates its end of the connection by sending a special message with the **FIN** (**finish**) bit set. This message, sometimes called a FIN, serves as a connection termination request to the other device, while also possibly carrying data like a regular segment. The device receiving the FIN responds with an acknowledgment to the FIN to indicate that it was received. The connection as a whole is not considered terminated until both sides have finished the shut down procedure by sending a FIN and receiving an ACK.

4. Choose a packet from your experiment as an example.

10.0.0.3	15t	10.0.0.1	TCP	74 38226→8700 [SYN] Seq=0 Win=29200 Len=0 MSS=1460 SACK_PERM=1 TSval=2655519 TSecr=0 WS=512
10.0.0.	2nd	10.0.0.3	TCP	74 8700→38226 [SYN, ACK] Seq=0 Ack=1 Win=28960 Len=0 MSS=1460 SACK_PERM=1 TSval=2655520 TSecr=2655519 WS=512
10.0.0.3		10.0.0.1	TCP	66 38226→8700 [ACK] Seq=1 Ack=1 Win=29696 Len=0 TSval=2655521 TSecr=2655520

(a) What is the value of window size?

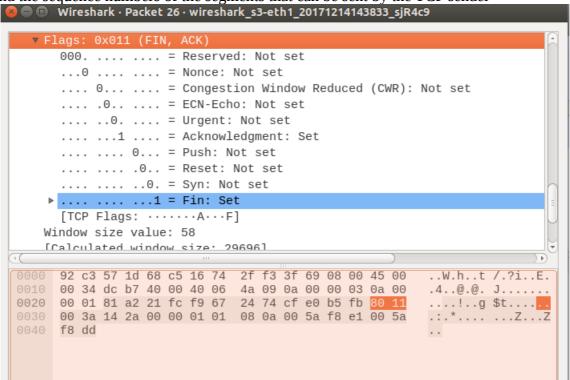

Window size is 29200 as the picture shown above.

(b) What is it used for?

It is used for flow controlling in TCP

(c) Find the sequence numbers of the segments that can be sent by the TCP sender

ExpBonus

Find and mark the interface names of switch on the topology you created in previous experiments. (Mark the names on the green labels of the following picture.)

Ans:

Consider the time sequence of wireshark from top to down of sending the data b/w h1,h3 with the following picture.

The data is transmitted in the blue line, either from h1 to h3 or from h3 to h1

Take an example of data from h1 to h3, the only road the data does not pass is s2h2, hence path of data transmission is $h1s1 \rightarrow s1s2 \rightarrow s2s3 \rightarrow s3h3$ using this sequence, I can identify the label of each interface if the switch.

The following picture shows the result, and timing from start to end.

(Note, the time sequence does not listed in ascending order since there are many switch interfaces to be detected by the wireshark at the same time, however, we can still find the connectivity of the topology where each of the interface of the switch should be.)

```
    ■ 111 14.018333000 10.0.0.3 10.0.0.1 TCP 74 45544→8700 [SYN] Seq=0 Win=29200 Len=0 MSS=1460
    ▼ Frame 111: 74 bytes on wire (592 bits), 74 bytes captured (592 bits) on interface 0
        Interface id: 0 (s1-eth1)
```

First, h1s1 and the label is s1-eth1

```
    ■ 122 14.021747000 10.0.0.3 10.0.0.1 TCP 66 45544 → 8700 [ACK] Seq=1 Ack=1 Win=2
    Frame 122: 66 bytes on wire (528 bits), 66 bytes captured (528 bits) on interface 1
    Interface id: 1 (s1-eth2)
```

Then s1s2, first through s1-eth2

```
■ 130 14.015688000 10.0.0.3 10.0.0.1 TCP 74 [TCP Spurious Retransmission] 455

▼ Frame 130: 74 bytes on wire (592 bits), 74 bytes captured (592 bits) on interface 3

Interface id: 3 (s2-eth2)
```

Then the s2-end part of s1s2, s2-eth2

```
    ■ 140 14.013102000 10.0.0.3 10.0.0.1 TCP 74 [TCP Spurious Retransmission] 45544 → 8700 [SYN] Sec
    Frame 140: 74 bytes on wire (592 bits), 74 bytes captured (592 bits) on interface 4
        Interface id: 4 (s2-eth3)
```

Then s2s3, first through s2-eth3

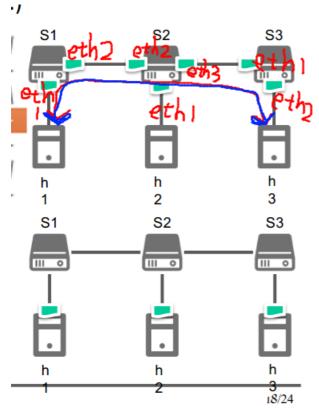

Then the s3-end part of s1s2, s3-eth1

And finally reach end

This is what the answer should be

2. How do you observe the packets passed through

the interface of h1?

Ans:

Use the filter with dst addr or src addr==10.0.0.1 (h1 is the server) in wireshark
